Climate and Features

The climate in the Taiga biome ranges from -65 to 70 degrees.

The taiga lies just south of the arctic circle.

Global warming can affect the biome by driving away the native species and causing flooding, which is caused by the lack of drainage.

Native Species

Some of the species that live in the taiga biome include bears, wolves, lynx, squirrels, caribous, moose, reindeer and minks.

Threats to the Biome

Some of the many threats faced by this biome are global warming, non-native species, flooding, and deforestation. These things can ruin the biome severely and possibly ruin the beauty of it.
